

ABSTRACT

A self sealing form that obviates the need of an envelope, and that is suitable for feeding into any type of printer. Thus, different embodiments are possible for continuous and non-continuous fed printers, which can be efficiently processed, as the message and addressing information are simultaneously printed, and only one trip across the printer is required, which is achieved by one single computer command by user. In general terms, different facing sections of the form have layers of adhesive and layers of a release substance arranged in such a manner that when they are in contact with one another, the layers of adhesive face the layers of release, allowing a temporary sealing, and then the positioning of another section of the form between the facing sections, enables the sealing of the form. Discretionarily, the form can also be processed manually.
